# Twitter Thread by Nik Kalyani

Newcomers to #crypto generally face one big problem — since we use a lot of jargon, many fundamental concepts are hard to understand.

I'm going to attempt to simplify things with plain English explanations for many crypto concepts.

Let's start with: #Wallets

# ∎/1

Blockchain data can be freely read by anybody with the right tool, usually a web app written by a developer.

But in order to make a change to blockchain data such as sending funds to someone or minting an NFT, you need to send a "transaction" to the blockchain.

## **/**2

A "transaction" (Tx) is an action that changes blockchain data. It has four primary components:

- 1■ What the Tx will do? (ex: transfer funds)
- 2■ Information needed for the Tx? (ex: amount, recipient)
- 3■ Tx fees (aka "gas")
- 4■ Authorization for the Tx via a digital signature

### **/**3

A digital signature here isn't just your scribbled signature in picture form. It specifically means using cryptographic techniques to create a sealed digital envelope that mathematically proves that "you" approved the Tx.

The "you" in this case is not you, the person.

"You" really means someone or something in possession of a special piece of information called a "private key"

The private key is a secret piece of information associated with your blockchain account that is used by a special tool to digitally sign the sealed Tx envelope.

#### **/**5

The commonly used name for the special tool that is used to sign the sealed Tx envelope is...

#### Wallet

In a nutshell, a crypto Wallet is a tool used to manage a list of accounts and their private keys that are necessary to sign blockchain transactions.

#### ∎/6

You're probably thinking, "But wait, Nik. That doesn't sound right. My crypto Wallet contains my BTC, ETH, NFTs, Doge ■. Your definition of Wallet doesn't mention how my crypto is stored in it. What gives?"

That friends, is the biggest misconception about crypto Wallets.

∎/7

Repeat after me — crypto Wallets do NOT contain any crypto assets. No coins. No tokens. No NFTs.

Crypto Wallets are a tool to manage your accounts and private keys - that's it.

Your crypto assets are ALWAYS data entries on the blockchain ledger, not in your crypto Wallet

#### ∎/8

This means you can use any number and type of crypto Wallets to transact for an account whose private key you know, and it will work swimmingly.

Your cryptocurrency — not in your Wallet Your tokens — not in your Wallet Your NFTs — not in your Wallet

So where are they?

#### **/**9

Your crypto assets are actually just blockchain data:

Coins you own — an entry for your account in the ledger of the blockchain on which that Coin is a native cryptocurrency

Tokens and NFTs you own — an entry for your account in the Smart Contract that issued the token

**/**10

Summary:

A crypto Wallet is a tool used to manage blockchain accounts and associated private keys.

Crypto assets are never in a Wallet, they always remain on the blockchain.

You can use multiple Wallets for the same account — just the UI will be different not the data.
