Nature news article July 2021

https://www.nature.com/articles/d41586-021-01693-6

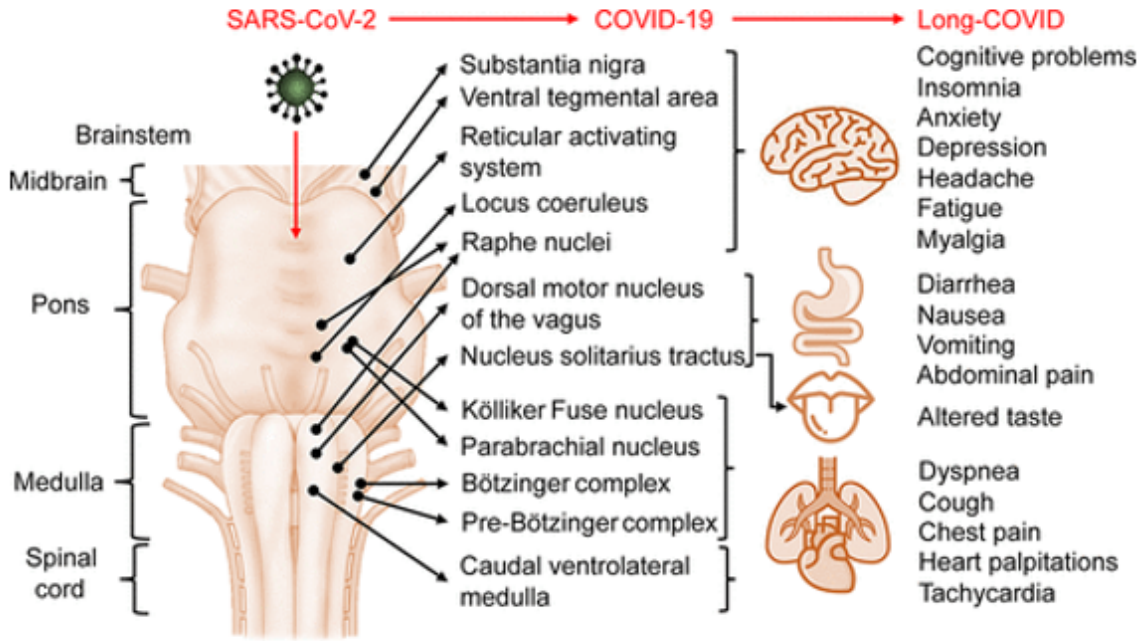

- "How COVID-19 damages the brain is becoming clearer. New evidence suggests that the coronavirus's assault on the brain could be multipronged: it might attack certain brain cells directly, reduce blood flow to brain tissue or trigger production of immune molecules that can harm brain cells.
- Infection with the coronavirus SARS-CoV-2 can cause memory loss, strokes and other effects on the brain.
- With so many people affected — neurological symptoms appeared in 80% of the people hospitalized with COVID-19 who were surveyed in one study[1] — researchers hope that the growing evidence base will point the way to better treatments.
- *"There is also growing evidence that some neurological symptoms and damage are the result of the body's own immune system overreacting and even misfiring after encountering the coronavirus."*

Pathological studies of microvascular injury in the brains of patients who died from Covid-19

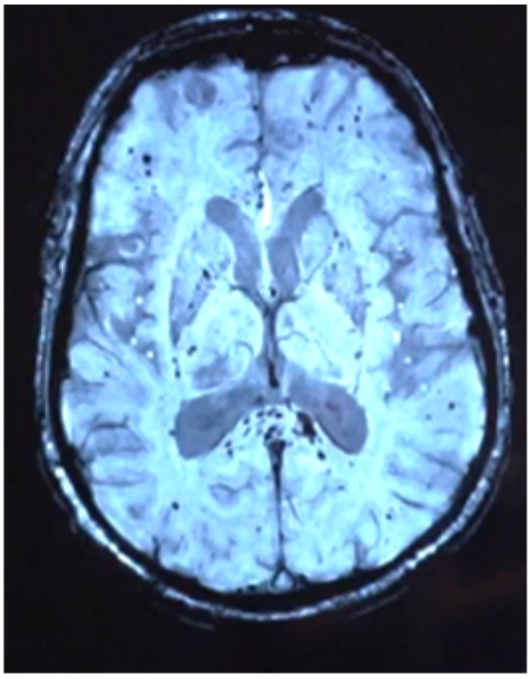

https://www.nejm.org/doi/full/10.1056/NEJMc2033369

Several patients
Panel A (magnetic resonance microscopy of the olfactory bulb) shows an area of hyperintense signal (arrow).
Panel B immunofluorescence imaging -> fibrinogen leakage (in the box, fibrinogen is shown in green, collagen IV yellow, and nuclei blue.
Panel B1 leakage of fibrinogen in the parenchyma Panel B2 an enlarged view blood vessel staining for collagen IV.
Panel C magnetic resonance microscopy of the pons
Panel D (fibrinogen staining) vascular leakage
Panel E collagen IV shows fibrinogen leakage in blood vessels
Panel F shows magnetic resonance microscopy of the medulla in Patient IA3. The yellow arrows indicate linear hypointense signals, and the red arrows indicate linear hyperintense signals.
Panel G-N Stained brain tissue postmortem.
Panel G CD68+ perivascular macrophages in the pons
Panel H astrocytosis in the basal ganglia
Panel I perivascular CD3+ cells in the cerebellum. Panel J CD8+ cells in the pons
Panel K perineuronal IBA1 cells in the pons
Panel L CD68+ cells in the dorsal motor nucleus of the vagus nerve
Panel M a solitary nucleus in the medulla
Panel N a pre-Bötzinger complex (Diaminobenzidine staining was used in Panels G through N.)

Plasma concentrations of blood-based CNS biomarkers in patients with mild, moderate, and severe COVID-19 compared to healthy controls

Biomarkers for CNS injury go up with covid

After about 6 months back to normal!

New damage stops, but permanent damage likely remains

Plasma concentrations of blood-based CNS biomarkers in patients with mild, moderate, and severe COVID-19 compared to healthy controls

Concentrations increased from a median of 20 (IQR 11–24) pg/mL in the first to 32 (IQR 16–60) pg/mL in last specimen (p = 0.002, figure 2D).
Plasma NfL concentration correlated inversely with the blood lymphocyte count, a negative prognostic factor11 (r = −0.37, p = 0.047); there was no significant correlation with C-reactive protein concentrations (data not shown).

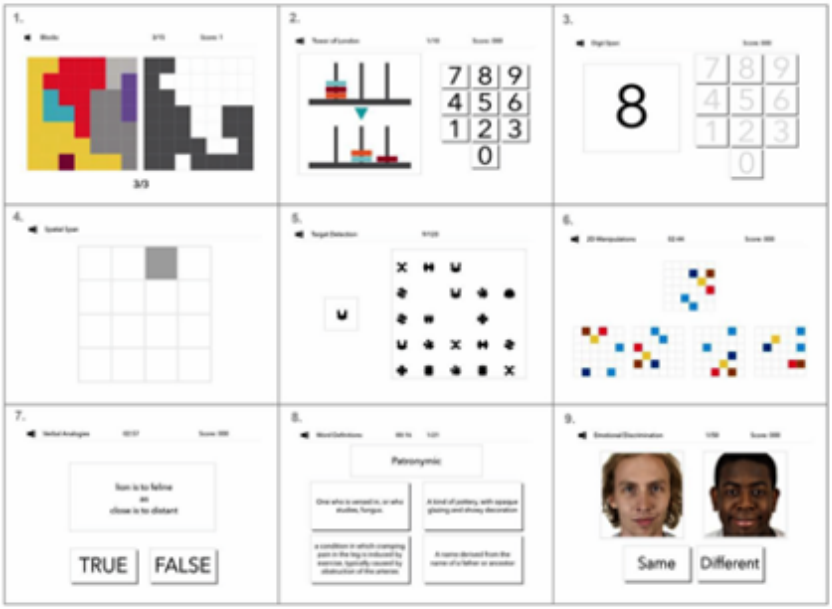

Discussion

We have examined 2 blood-based biomarkers for CNS injury in patients with COVID-19. NfL and GFAp have historically been proven to be useful measures of CNS injury when assessed in CSF, but sampling of this fluid is challenging in the clinical COVID-19 setting. In contrast, measurement of these markers in the plasma is convenient and provides a practical method of
(A and B) Log10 plasma levels were analyzed with analysis of covariance, including interactions between age and group. Estimated geometric means at 70 years of age for the 3 coronavirus disease 2019 (COVID-19) groups were compared with controls. (A) Age and plasma glial fibrillary acidic protein (GFAp) were significantly correlated. Plasma levels of GFAp were significantly increased in the moderate and severe COVID-19 groups compared to controls (p = 0.03 and p = 0.001, respectively). (B) Age and plasma neurofilament light chain protein (NfL) were sig- nificantly correlated. Plasma levels of NfL were 3.1 times higher in patients with severe COVID-19 compared to controls (p < 0.001). (C) Correlation between log10 values of plasma GFAp and NfL in patients with COVID-19.

Neurocognitive long-COVID

- Neurocognitive long-COVID symptoms can persist ≥1 year after COVID-19 symptom onset and reduce life quality significantly. Several neurocognitive symptoms were associated with ANA titer elevations. This may indicate autoimmunity as a cofactor in etiology of long COVID.

Even mild cases of COVID-19 leave a mark on the brain

Loss of grey matter after Covid infection

COVID patients were scanned before and after they contracted the disease
UK Biobank project, and its COVID-19 re-imaging study

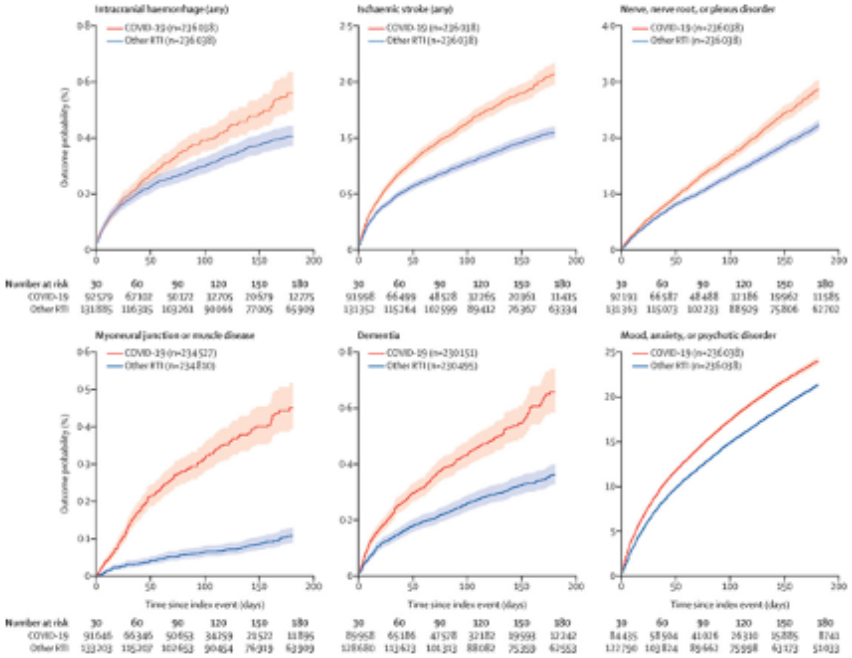

Most significant longitudinal group comparison results.
3 main regions showing significant loss of grey matter (thickness, volume) between the two timepoints specifically for the COVID patients are the parahippocampal gyrus, the lateral orbitofrontal cortex, and the superior insula. All results were localised to the left hemisphere. For each region, the IDP spatial region of interest shown in magenta, overlaid on the FreeSurfer average inflated cortical surface; to the right are the scatter and box plots showing the difference in cortical thickness or volume between the two timepoints for the 388 controls and 394 COVID patients. In black circles are the 15 hospitalised COVID patients. All y axes are arbitrary units proportional to the original measures, due to the normalisation steps in the IDP preprocessing.

Psychiatric outcomes increase after covid infection

Among 236 379 patients diagnosed with COVID-19, the estimated incidence of a neurological or psychiatric diagnosis in the following 6 months was 33·62% (95% CI 33·17–34·07), with 12·84% (12·36–13·33) receiving their first such diagnosis. For patients who had been admitted to an ITU, the estimated incidence of a diagnosis was 46·42% (44·78–48·09) and for a first diagnosis was 25·79% (23·50–28·25).

Similar patterns of 18F-FDG brain PET hypometabolism in children (and adults) with long COVID

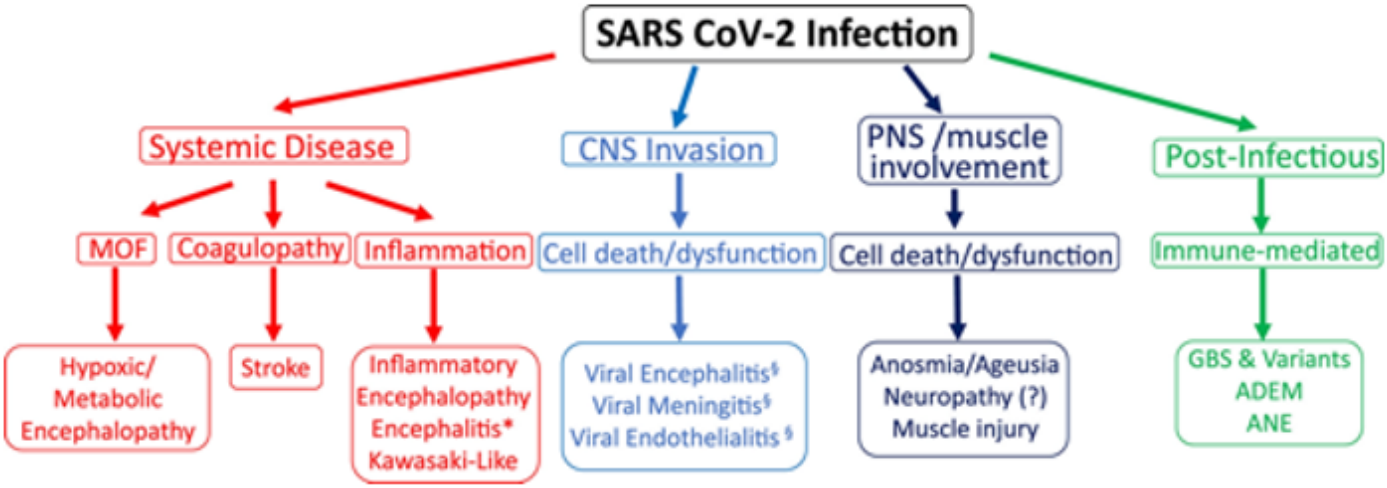

Individual 18F-FDG PET of each of the seven children patient (#1 to #7), including the follow-up of two of them (#4b and #7b) An example of normal PET metabolism in a child of 10 years old is also presented. Hypometabolism is found in olfactory regions for children #1,3,4,5,6; in temporal regions for children #1,3,4,5,6,7; in the brainstem for children #1,3,4,5,6,7; in the cerebellum for all children. At follow-up, the brain metabolism was improved at least for the brainstem.

COVID-19: A Global Threat to the Nervous System

- FIGURE: Mechanisms of severe acute respiratory syndrome-coronavirus type 2 (SARS-CoV-2) neuropathogenesis. SARS-CoV-2 pathogenic effects on the nervous system are likely multifactorial, including manifestations of systemic disease, direct neuro-invasion of the central nervous system (CNS), involvement of the peripheral nervous system (PNS) and muscle, as well as through a postinfectious, immune-mediated mechanism. MOF = multi-organ failure; GBS = Guillain-Barre syndrome. *CNS in□lammation (CSF pleocytosis and proteinorrachia) with no evidence of direct viral infection of CNS; direct evidence of viral invasion (reverse transcriptase-polymerase chain reaction positive [RT-PCR+], biopsy); ADEM = acute disseminated encephalomyelitis; ANE = acute necrotizing encephalopathy.
