The Dutch Protocol is the basis on which the entire puberty blocking experiment rests.

For this experiment they used two scales, a boy scale and a girl scale and these two scales asked very different questions. 1/4

Before intervention, they assessed children using a sex-congruent GD scale.

Post-intervention they switch to the opposite sex scale.

Does this accurately assess changes in the participants' gender dysphoria? <https://t.co/YSiUQpfMCZ>

The first scale asked a distressed girl whether she liked looking like a girl, doing girl things etc. Then the second time round, after treatment, they used the boy scale and asked this biological girl if she liked looking like a boy and doing boy things. 2/4

So for the first scale the answers were a hard no, and she scored high for gender dysphoria. Then the second time round the answers would be a hard yes, and so she'd score low for gender dysphoria. And the presumption was that the treatment NOT the insane switching of scales 3

that brought about the low score for gender dysphoria.

The entire basis of the supposed success of puberty blocking treatment all around the world is based on this so called "reduced gender dysphoria" which is measured by this use of girl and boy scales. 4/4
