An Introduction to Price and Volume Action (thread)

An understanding of price and volume action is essential for judging supply and demand characteristics. This allows you to determine whether a stock is under accumulation or distribution and find proper buy and sell points

This thread is not about memorizing candlestick patterns, but instead understanding how supply and demand create patterns over and over again. The Stock Market is an auction, and the large buyers and sellers leave clues for us to find within price and volume.

Let's start with one price bar. I personally use OHLC charts but feel free to use what makes sense to you, they each present the same information. A single bar can represent a minute, 15 minutes, a day, or a year. The higher the timeframe the more meaningful the price move.
I view each bar as a match of tug of war between the buyers and the sellers. Buying pressure tries to pull the stock price up while selling pressure tries to pull it down. The winner is reflected in the closing range.

The closing range (CR) represents where the close is within the range of the high to the low. The closer to 100% on an up day the stronger the action. After a day with a closing range in the high 90s, the expectation is that the momentum will continue into the next day.

$$ClosingRange = \frac{Close - Low}{High - Low}$$

It is also important to compare the price action to that of the overall market. If $AAPL has a daily CR of 85% when the $SPY has a DCR of 15%, that is a clue that $AAPL is outperforming within that time frame. This is a sign of Relative Strength

Also during a base or general market weakness, a weekly closing range of 40% or higher is a sign of strength. You can see this in $NVDA during the March Crash. During 3/4 of the down weeks, it had a relatively strong CR suggesting institutions were supporting it.
Now with every bar you also want to consider volume. Volume adds weight to what price is doing. A stock up 20% finishing at the highs of the day on higher volume confirms that institutional money is behind the move.

High Volume Up day

5Y 1Y YTD 6M 3M 1M 1W 1D Today

The next day you had tight price action on lower volume. There is a balance between buyers and sellers here as supply is absorbed. You also had a strong closing range on this down day.

However if the next day the stock reverses on higher volume that is a negative expectation breaker. You have to take it day by day. Sellers were stronger here.
The same is true on the downside. A large down day finishing near the low on high volume is a bad sign and suggests further downside.

However a down day with a decent CR or "low volume" suggests supply is being absorbed, especially if the price action is tight.

But what is "low volume"? I judge volume based on the average of the past 50 days and I also compare it to the previous 10 days. If on an up day volume is higher than any down volume within the past 10 days that's a subtle sign of accumulation. I color those bars blue.
When looking at a stock chart it's as simple as this, I want to see as many blue bars or above average up days within the recent action and very few above average red volume bars.

I also use the Up/Down Volume ratio to judge accumulation. The U/D Ratio is the ratio of up volume days to down volume days in the last 50-day period. You want that to be greater than 1 and the higher the better.

Now let's zoom out just a little. A stock will go through periods on consolidation/price contraction and then sustained trends. During the uptrends especially on a weekly chart, you want to see good weekly closing ranges ideally on high volume.

And during the bases and sideways consolidations you want to see lower volume and still good closes ideally.

Decreasing Volume Within the Base

5Y 1Y YTD 6M 3M 1M 1W 1D Today

These pauses/bases are normal as short-term holders take profits and for the moment there is a balance between buyers and sellers. Usually if there are no major signs of distribution and the stock is still early in its run, the stock will continue its uptrend after the base.

During a base you want to see price coiling tighter from left to right making higher highs and higher lows. At the same time, you want to see volume decrease. This indicates that institutions are absorbing supply and buying aggressively if the stock drops even a little.

This is called a volatility contraction pattern (VCP) coined by Mark Minervini. From a base like this a stock can explode upwards very quickly because all the supply has been absorbed and any increased demand will drive up the stock price.

These same principles apply on a larger timeframe. I focus on stocks near or hitting new all time price highs. As William O'Neil Said

"It is one of the great paradoxes of the stock market that what seems too high usually goes higher and what seems too low usually goes lower."

-William O'Neil

This may seem counter intuitive but its all due to supply and demand. When a stock is hitting all time highs everyone who owns it and is buying more is in the green. The only reason selling occurs is to cash in profits.

FSLY Daily ▾   Vol at Price ▾

No one owns it above this level waiting to sell at breakeven

Breakout Into All Time Highs

FSLY Increased 98% in 24 days from this point

5Y 1Y YTD 6M 3M 1M 1W 1D Today

However when a stock is well of it's highs, as soon as it tries to rally upwards it hits selling from everyone who bought higher tying to sell at breakeven, this is called overhead supply.

So in summary, supply in demand is what drives price and volume action. Learning to recognize whether buyers or sellers are in control takes time but once you can do that you increase your odds of finding stocks under accumulation and buying when demand overwhelms supply.

I hope this was helpful. Feel free to checkout some of my other threads
