The @dailymaverick asked me to do a piece on the trans woman in sport issue. It's necessarily short and high level, but here it is. Writing it made me realize there are some key questions everyone who wades into the debate upfront should answer. Wanted to share them here (1/\_)

# Gender games: The complex issue of sport categories and why they matter

Global sporting bodies are wrestling with legal, moral and ethical questions over transgender athletes and where they fit in. It's an emotive issue with no easy answers across a wide range of sporting codes. By Ross Tucker

In October, World Rugby became the first major Olympic sporting code to issue a policy that prevents transgender women from playing women's rugby. The policy caused seismic tremors in a sporting world that is grappling with the issue. Court cases and legislation in the US, the prospects of the first trans women medalists in the Olympic Games, and a growing lobby on both sides of the issue have created an incendiary climate in which to discuss the philosophy, biology and human rights elements of what is sport's most complex issue.

Also, in the last month, Caster Semenya announced that she would continue to challenge the World Athletics' regulations that compel her to lower her testosterone levels in order to be eligible to compete in her favoured running events.

Next stop, the European Court of Human Rights, after failed attempts at the Court of Arbitration for Sport and the Swiss Federal Tribunal. It is unknown how long the process may take, and it may well be that Semenya's career as an 800m runner ends while the appeal is ongoing, but her case is another example of how sport is battling with its handling of biological sex and women's sport.

## Trans and DSD

To be clear, Semenya is not trans. Rather, she has a DSD, a Difference of Sex Development, which means she does not use testosterone in the typical way. Women with DSDs differ from trans women in important ways that have some physiological implications, and perhaps more importantly the medical ethics of how a policy is actually implemented for that population. If anything, the DSD case is more complex.

What the trans and DSD issues do share, however, is a principle or physiological premise that demands thought and consideration of why women's sport exists, and whether inclusion into that category should be considered, and how. World Athletics won the Semenya case because of this principle, and World Rugby's policy arrived at an evidence-based recommendation that reinforces it.

Simply, it argues that a woman's category "protects" the integrity of the result for biological females and in some instances, the safety of its participants. Biological females do not possess the same physical attributes as males and many of these male-bodied attributes have profound implications for sports performance.

So, while the women who win Olympic medals and world titles would outperform most men in most sports, they are vastly outperformed by the males who win the equivalent Olympic medals and world titles.

In the comparison group that matters, there is literally no contest. Take for instance the fact that the best women runners in history are outperformed every year by hundreds of boys younger than 18, and by many thousands of adult men.

The gap between the respective champions in most track and field disciplines is 10% to 12%, and thousands of biological males fit into that space. As a result, if women's sport did not exist as a category, women would vanish entirely from elite track and field.

Consider next that a 10% to 12% difference is actually relatively small. In weightlifting, the difference is 30% to 40%. For tasks like serving in tennis, it is 20% and for punching power, the male advantage has been measured at 160%.

These differences are enormous and within a relevant comparison group (like Olympic athletes, or high school athletes competing for scholarships), they are insurmountable.

This is not to say that female athletes do not possess extraordinary abilities, as well as technical and mental skills that are necessary in champions. But male-bodied physiological advantages are so large that all attributes unrelated to biological sex, the ones that should actually matter, are drowned out by things like muscle mass, strength, power, body shape and speed.

## The major differentiator

The biological basis for these differences is testosterone. Not exclusively, of course, but primarily, this hormone is responsible for all the changes we easily recognise in young boys as they move through puberty to become adults.

Many have direct implications for sport – more muscle, less fat, a narrower and longer skeleton including larger hands, a longer skeleton and lungs, and more haemoglobin to transport oxygen around the body. These create more power and speed, greater strength and endurance, and mechanical advantages in sports where height, arm length and hand size matter.

On a biological level, then, women's sport exists so that we can reward, as equally deserving, two humans who possess "the right stuff" for a given event, even though their performances are different.

When Wayne van Niekerk and Shaun Miller-Tibbo both receive Olympic 400m gold medals, sport is saying that it under-

terone, but identify as female. What is their place in sport?

A decent and progressive society accepts them. But can sport accept them into the protected, closed category for women? Given the biological realities, if self-identification or gender identity were the sole criteria, women's sport would become "open", and its purpose negated.

This then sets up what is basically a "colliding rights" issue, where the rights of females to have a sporting space of their own collides with the rights of other individuals to identify as they wish. Sport finds itself in the middle of that collision. It becomes, effectively, a question of how various priorities are balanced. Those priorities are inclusion, fairness and, in some sports, safety.

Historically, the approach to this issue has been relatively simple – it tried to "fix" the problem by relying on medication or surgical intervention to lower the testosterone levels in trans women.

Given what we described above regarding testosterone's crucial role in creating the male-female sporting divide, the premise is that if testosterone is lowered or removed, so is the sporting advantage.

The lowering of testosterone can be achieved either through surgical removal of the testes that produce it, or, as per the most recent Olympic transgender policy, medication that lowers the testosterone below a target level for a period of 12 months.

But this approach is controversial for obvious reasons. Compelling an otherwise healthy individual to use drugs as a requirement to participate, which may have serious side effects, is straddling an uncomfortable ethical line.

Even if the athlete accepts this approach, the acid test, then, is whether the outcome is true. Does the suppression of testosterone take away those differences that women's sport excludes?

If the answer is "yes", then sport is in the happy position of achieving inclusion, fairness and safety. But if the answer is "no", then sport has a dilemma, because those three imperatives can no longer be balanced or held equally by the same policy.

low some sports to balance inclusion and fairness, but for sports where mass, size, strength, power and speed matter, the evidence all points one way, in the direction of retained advantage and the necessity of a prioritisation of those imperatives.

## Legalities of the case

That decision is then informed by matters of risk and legal considerations. If player welfare is a priority, then the imposition of foreseeable and unreasonably high risks on a group of players by virtue of, in this case, failing to protect a sex class in sport cannot be justified.

Many countries have gender recognition acts that stipulate that sports can restrict participation, and effectively discriminate on the basis of sex if the sport is "gender-affected", which rugby most certainly is.

While a policy that excludes trans women from playing women's rugby may invite legal challenges against discrimination, not doing so could invite both discrimination claims by biological females and, possibly, claims that arise out of injuries, potentially serious. Given that World Rugby regularly states that its number one priority is player welfare, the decision was made, led by the evidence and principle, that trans women cannot currently play elite women's rugby, with Member Unions given the option to comply or not, depending on local legislation.

## Ignorance is not an option

It is an immensely difficult decision, but one that all sports must confront. To date, sporting bodies have appeared to hope that the fix works and have ignored a host of studies that suggest it doesn't.

Their fallback is often: "there is no research into elite athletes, no evidence of advantages for trans women". The problem with this approach is twofold.

First, there is now enough evidence in non-athletic groups to suggest a problem that would persist even when elite training is added to the mix. For various technical reasons, training is likely to exacerbate the problem, not remove it. Sports can't ignore that body of evidence, even if they don't deem it directly relevant to them.

Second, adopting a position of inclusion on the (false) basis that there is no evidence at all implies that women's sport should be treated as open, allowing biological males into it and then evidence should be sought to disprove it.

This is certainly an approach that one might defend on the basis of human rights. Others would argue that the category should be closed until evidence is provided to show that opening it can be done without safety and fairness implications for women.

Regardless, this is not a problem that will disappear, and in time, sports may be confronted not only by evidence and principles, but specific high-profile cases, perhaps as soon as the 2021 Olympic Games.

It is not melodramatic to say that the future of women's sports depends upon how science, human rights and sporting imperatives are managed in this most complex controversy. DM168

The first question, before any other "shots are fired", should be:

"If there is ZERO evidence for what happens to performance and/or biology in trans women undergoing treatment, what should happen for sport? Would you allow inclusion, or would you exclude until it exists?" (2/)

This is so important because it reveals a “value system” and understanding of women’s sport. If you believe in inclusion in the absence of evidence, you’re saying that women’s sport should be OPEN to self-ID, and then evidence must be provided to prove unfairness or risk. (3/)

On the other hand, if you say exclusion until evidence exists, you’re stating that women’s sport should remain CLOSED unless evidence can be provided to assure its participants that it is fair and safe to open it to athletes who have benefited from T during development (4/)

Once you’ve answered this first question, then you move to number 2, which is:

“The current policies for inclusion require suppression of T for 12 months, in order to allow participation without unfairness or harm. How strong is the evidence that this is actually achieved?” (5/)

Here’s where it gets as tricky as you want it to be, and you can act in bad faith to say “Ah, we are so helpless, there is no good research in athletes to answer this, we simply can’t say”. Which is why your answer to Q1 is important. However, such self-despairing pity is also...

...not even true, because there are some studies. In runners, there are 2 studies, neither particularly good. One finds that in 8 runners, with self reported times, spanning two decades, with no controls, no report of training, or even T levels, performance advantages are removed

The other showed that in DSD athletes who can use T, the suppression of T slowed performance by 5.7%, which is half the typical male advantage. So you could call it 1-1, but really neither study is very good. So then you find some good studies. (7/)

Those good studies are unfortunately not directly in athletes, but they are the ones that should really make sports organizations sit up and take notice. They show, without exception, that trans women who have suppressed T lose only small amounts of mass, muscle mass & strength

The result is a retained advantage over the correct reference group of females. The problem, of course, is that these comparisons are in non athletes, so both baseline and subsequent training induced changes are not directly assessed. But go back to Q1 now. Remember we said ZERO

...evidence, right? Well there’s NOT zero evidence. There’s actually a lot to suggest retained advantages, and when you look at published literature you find that training may make these even larger. How sport & scientists can ignore these is astonishing. It’s 12-0 on evidence

However, you may still hold that line, that there’s zero (or maybe you think insufficient) evidence, and so this inclusion should be the default. Which is fine, but that’s what should be stated upfront. Basically, you have to declare whether women’s sport is Closed or Open (11/)

Then you have to evaluate the “fix” - testosterone suppression. If you think it works to create fairness, safety AND inclusion, you’re ignoring a dozen studies that point in exactly the opposite direction. Now you have to treat women’s sport as open AND ignore evidence (12/)

All of which would make me wonder what the agenda is? Inclusion at the expense of all else? Ok cool, but then own it, and say "I think women's sport should be open, despite available contradictory evidence with limitations, and I don't care about fairness and safety of females".

At least if you did that, it would frame subsequent disagreements, would be honest, and your position could earn some respect. But to pretend you're holding up "scientific evidence" as a basis for inaction & then ignoring that which strongly suggests the fix doesn't work? Come on

So if you believe in "open women's sport to biological males until evidence shows we shouldn't", say so at the start, save us debate time. If you believe it should be closed, but also in inclusion, let me know which evidence you think supports this, I'd like to see it (13/13)
